 (February 1, 2008)

We have applied the variational R -matrix method to calculate the reflection and tunneling probabilities of particles tunneling through one-dimensional potential barriers for five different types of potential profiles – truncated linear step, truncated exponential step, truncated parabolic, bell-shaped, and Eckart. Our variational results for the transmission and reflection coefficients are compared with exact analytical results and results obtained from other numerical methods. We find that our results are in good agreement with them. We conclude that the variational R -matrix method is a simple, non-iterative, and effective method to solve one-dimensional quantum tunneling problems.

I. INTRODUCTION

Quantum tunneling is of considerable interest in modern physics [1]. Tunneling of particles through potential barriers have applications in different areas such as radioactive decay [2], black hole production [3], optical wave-guides, lasers, quantum well structures [4], and electron transport in micro and nanoscale devices [5]. In fact spin polarized tunneling in semiconductor and magnetic heterostructures has opened up a new area in condensed matter physics, known as “spintronics” [6].

The tunneling coefficient is the key element of the tunneling process that must be understood. For example, in the case of nano-devices it determines the current-voltage characteristics. In a tunneling problem one usually solves for the tunneling coefficient by solving the Schrödinger equation with appropriate boundary conditions. But there are only a few potentials for which the Schrödinger equation can be solved analytically so that exact results for the tunneling coefficients can be obtained. Other potentials must be solved numerically using techniques such as the Wentzel-Kramos-Brillouin (WKB) [2], modified conventional WKB (MWKB) [7], modified Airy function (MAF) [8], numerical matrix (MAT) [9], transfer matrix (TM) [10], and R -matrix [11] methods. All these techniques have been employed to calculate the transmission coefficients for different types of potential barriers.

The R -matrix method was originally developed by Wigner for use in nuclear physics [12]. Later his method was extended by others to solve a variety of different problems in atomic and molecular physics [13–16]. A variant of the R -matrix method known as the variational R -matrix method, has been successfully applied recently to the problem of quantum tunneling through a potential barrier [17].

In this paper, we report on our test of the effectiveness of the variational R -matrix method in obtaining the

transmission coefficients for a variety of one-dimensional potentials of interest. We find our variational results to be in good agreement with existing analytical and numerical results.

In Sec. II we briefly present the variational R -matrix method. In Sec. III we apply the method for particle tunneling through potential barriers. Our results are compared to results from analytical expressions and other numerical methods. The results are summarized in Sec. IV.

II. FORMALISM

In this section, we briefly outline the variational R -matrix method following Ref. [17]. We begin with the one-dimensional time independent Schrödinger equation for a particle of mass m and with energy E in a potential $V(x)$ (assumed to be real),

$$\frac{d^2\psi}{dx^2} + \frac{2m}{\hbar^2}[E - V(x)]\psi = 0. \quad (1)$$

As Eq. 1 is a linear and second order differential equation there are two independent solutions, ψ and $\tilde{\psi}$ with the same energy E . We define three regions: an inner region ($a \leq x \leq b$) where the potential is a function of the position x , and two outer regions defined by $x \leq a$ and $x \geq b$, where a and b are the boundaries separating the inner region II from the outer regions I and III.

In the regions I and III the potentials V_1 and V_3 are either zero or constant. So the wave-functions ($\psi_1, \tilde{\psi}_1$) and ($\psi_3, \tilde{\psi}_3$) are oscillatory and can be written in terms of exponential functions,

$$\psi_1(x) = a_1 \exp(ik_1x) + b_1 \exp(-ik_1x), \quad (2)$$

$$\tilde{\psi}_1(x) = \tilde{a}_1 \exp(ik_1x) + \tilde{b}_1 \exp(-ik_1x), \quad (3)$$

$$\psi_3(x) = a_3 \exp(ik_3x) + b_3 \exp(-ik_3x), \quad (4)$$

$$\tilde{\psi}_3(x) = \tilde{a}_3 \exp(ik_3x) + \tilde{b}_3 \exp(-ik_3x), \quad (5)$$

where $k_1 = \sqrt{2m(E - V_1)}/\hbar$ and $k_3 = \sqrt{2m(E - V_3)}/\hbar$. We assume $E > V_1, V_3$, so k_1 and k_3 are real. The coefficients $a_i, \tilde{a}_i, b_i, \tilde{b}_i$ ($i = 1, 3$) can be calculated by matching the wave-functions and their first derivatives at the boundaries, i.e. at $x = a$ and $x = b$.

In region II, we expand the wave-function in terms of a suitable set of N basis functions $\chi_i(x)$,

$$\psi_2(x) = \sum_{i=1}^N c_i \chi_i(x). \quad (6)$$

Here c_i 's are the variational coefficients. In all the cases we have studied we have used $\chi_i(x) = \cos(\kappa_i x)$ to be a simple basis set. The parameters κ_i 's are chosen by trial and error so that the basis functions $\chi_i(x)$ are sufficiently complete for our input energy values.

We set-up the R -matrix for region II by multiplying both sides of Eq. 1 with $\psi_2(x)$ and then integrate by parts to obtain,

$$-\int_a^b dx [\psi_2'(x)]^2 + \frac{2m}{\hbar^2} \int_a^b dx [E - V(x)] \psi_2^2(x) + \lambda(b) \psi_2^2(b) - \lambda(a) \psi_2^2(a) = 0. \quad (7)$$

In Eq. 7 we have defined the logarithmic derivatives of ψ_2 at $x = a, b$: $\lambda(a) = \psi_2'(a)/\psi_2(a)$, $\lambda(b) = \psi_2'(b)/\psi_2(b)$. We substitute Eq. 6 in Eq. 7, which now takes the form

$$Q = \sum_{i,j=1}^N [A_{ij} c_i c_j + \lambda(b) \Delta_{ij}^b c_i c_j - \lambda(a) \Delta_{ij}^a c_i c_j] = 0, \quad (8)$$

where $\mathbf{A}$, $\mathbf{\Delta}^a$, and $\mathbf{\Delta}^b$ are $N \times N$ real symmetric matrices defined as

$$A_{ij} = -\int_a^b dx \chi_i'(x) \chi_j'(x) + \frac{2mE}{\hbar^2} \int_a^b dx \chi_i(x) \chi_j(x) - \frac{2m}{\hbar^2} \int_a^b dx \chi_i(x) V(x) \chi_j(x), \quad (9)$$

$$\Delta_{ij}^a = \chi_i(a) \chi_j(a), \quad (10)$$

$$\Delta_{ij}^b = \chi_i(b) \chi_j(b). \quad (11)$$

Q in Eq. 8 does not change by varying c_i 's. Thus by taking the derivative of Q with respect to c_i and setting it to zero we obtain a set of equations that can be succinctly written in matrix form as

$$[\mathbf{A} + \lambda(b) \mathbf{\Delta}^b] \cdot \mathbf{C} = \lambda(a) \mathbf{\Delta}^a \cdot \mathbf{C}. \quad (12)$$

$\mathbf{C}$ is a column vector with elements c_i 's. Eq. 12 is a generalized eigenvalue equation which should yield exactly N real solutions. But the matrices $\mathbf{\Delta}^a$ and $\mathbf{\Delta}^b$ have rank one due to their peculiar structures [17], so Eq. 12 has a unique solution. We solve Eq. 12 using the computational

software MATLAB to obtain the eigen-vectors $\mathbf{C}$ and $\tilde{\mathbf{C}}$ for two different values of the logarithmic derivatives $\lambda(b)$ and $\tilde{\lambda}(b)$. Note that the values of the logarithmic derivatives $\lambda(\ell)$ and $\tilde{\lambda}(\ell)$ at a given point $x = \ell$ can be chosen arbitrarily [17]. In this paper, we have chosen $\ell = b$ for our calculations.

Thus, in region II, we obtain two linearly independent solutions $\psi_2(x) = \sum_{i=1}^N c_i \chi_i(x)$ and $\tilde{\psi}_2(x) = \sum_{i=1}^N \tilde{c}_i \chi_i(x)$. Next we use the continuity of the wave-functions and their first derivatives at the boundaries $x = a$ and $x = b$. These yield a set of four simultaneous equations

$$a_1 e^{ik_1 a} + b_1 e^{-ik_1 a} = \sum_{i=1}^N c_i \chi_i(a), \quad (13)$$

$$ik_1 (a_1 e^{ik_1 a} - b_1 e^{-ik_1 a}) = \sum_{i=1}^N c_i \chi_i'(a), \quad (14)$$

$$a_3 e^{ik_3 b} + b_3 e^{-ik_3 b} = \sum_{i=1}^N c_i \chi_i(b), \quad (15)$$

$$ik_3 (a_3 e^{ik_3 b} - b_3 e^{-ik_3 b}) = \sum_{i=1}^N c_i \chi_i'(b), \quad (16)$$

which we solve to evaluate the coefficients a_1, b_1, a_3 , and b_3 . We repeat the same steps to obtain the other set of coefficients $\tilde{a}_1, \tilde{b}_1, \tilde{a}_3$, and $\tilde{b}_3$. These coefficients and c_i 's completely determine the two independent wave-functions $\psi(x)$ and $\tilde{\psi}(x)$ for the entire region. We can now write the general solution for the entire region as a linear combination of these wave-functions, i.e. $\Psi(x) = B\psi(x) + \tilde{B}\tilde{\psi}(x)$ where B and $\tilde{B}$ are two arbitrary constants.

Next, we obtain expressions for the reflection and transmission coefficients. In region I, using Eqs. 2 – 5, the general solution can be written as

$$\begin{aligned} \Psi_1(x) &= B\psi_1(x) + \tilde{B}\tilde{\psi}_1(x), \\ &= (Ba_1 + \tilde{B}\tilde{a}_1) [e^{ik_1 x} + \rho e^{-ik_1 x}]. \end{aligned} \quad (17)$$

ρ is the amplitude for reflection and is given by $\rho = (Bb_1 + \tilde{B}\tilde{b}_1)/(Ba_1 + \tilde{B}\tilde{a}_1)$. Similarly for region III,

$$\begin{aligned} \Psi_3(x) &= B\psi_3(x) + \tilde{B}\tilde{\psi}_3(x), \\ &= [Ba_3 + \tilde{B}\tilde{a}_3] e^{ik_3 x} + [Bb_3 + \tilde{B}\tilde{b}_3] e^{-ik_3 x}. \end{aligned} \quad (18)$$

We consider the physical situation where we have an incident wave of unit amplitude (which implies $Ba_1 + \tilde{B}\tilde{a}_1 = 1$) coming from the left that partially penetrates the barrier and gets transmitted to region III. As there is no reflected wave in region III, we have another constraint $Bb_3 + \tilde{B}\tilde{b}_3 = 0$ on the coefficients B and $\tilde{B}$. By solving

these equations for B and $\tilde{B}$ we obtain the reflection and transmission coefficients. They are given by

$$R = |\rho|^2 = \left| \frac{b_1 \tilde{b}_3 - b_3 \tilde{b}_1}{a_1 \tilde{b}_3 - b_3 \tilde{a}_1} \right|^2, \quad (19)$$

$$T = \left(\frac{k_3}{k_1} \right) \left| \frac{b_3 \tilde{a}_3 - b_3 \tilde{a}_1}{a_1 \tilde{b}_3 - b_3 \tilde{a}_1} \right|^2. \quad (20)$$

A good check of the numerical accuracy of our calculation is to calculate the average energy E_{av} in region II ($a \leq x \leq b$) with the input value of the energy E . E_{av} can be evaluated using the expression

$$E_{\text{av}} = \frac{\sum_{i,j=1}^N c_i c_j P_{ij}}{\sum_{i,j=1}^N c_i c_j R_{ij}}, \quad (21)$$

where

$$P_{ij} = \int_a^b dx \left[-\frac{\hbar^2}{2m} \chi_i(x) \chi_j''(x) + \chi_i(x) V(x) \chi_j(x) \right], \quad (22)$$

$$R_{ij} = \int_a^b dx \chi_i(x) \chi_j(x). \quad (23)$$

III. APPLICATIONS AND RESULTS

In order to test the effectiveness of the variational R -matrix method we have chosen five different one-dimensional potentials: truncated linear step, truncated exponential step, truncated parabolic, bell-shaped, and Eckart. We consider particles coming from region I with total energy E ($E > V_1, V_3$) striking the potential barrier. According to quantum mechanics, there is a finite probability for the particles to be transmitted to region III even if the particles have energy less than the maximum height of the potential barrier. Particles that are not transmitted to region III are reflected back to region I. We use the variational method to calculate the reflection and transmission coefficients as a function of particle energies for each potential barrier.

For all cases we have checked the accuracy of our calculations by comparing the average energies calculated from Eq. 21 with the actual input energies. We also have compared our results with exact analytical results (ANA) and also with other numerical methods, such as numerical matrix (MAT) [9], transfer matrix (TM) [10], Wentzel-Kramos-Brillouin (WKB) [2,8], modified conventional WKB (MWKB) [7], modified Airy functions (MAF) [2], and improved MAF (MMAF) [18].

A. Truncated linear step potential

The truncated linear step potential barrier is a practical example of a potential encountered in planar waveguides [19]. It is defined by the potential function

$$V(x) = \begin{cases} 0, & x < a \\ V_0(B-x), & a \leq x \leq b \\ 0, & x > b \end{cases} \quad (24)$$

which is shown in Fig. 1.

FIG. 1. Truncated linear step potential with $V_0 = 0.5$ hartree, $B = 3$ bohr, and boundaries at $x = 1$ bohr and $x = 3$ bohr.

For the truncated linear step potential the Schrödinger equation can be solved analytically to obtain the wavefunction [20]. The exact solution for the inner region can be written in terms of the Airy functions $Ai(x)$ and $Bi(x)$ [21],

$$\psi_2(x) = a_2 Ai \left(\alpha^{1/3} [B - x - \epsilon] \right) + b_2 Bi \left(\alpha^{1/3} [B - x - \epsilon] \right), \quad (25)$$

where $\alpha = 2mV_0/\hbar^2$, $\epsilon = E/V_0$, and a_2 and b_2 are coefficients to be determined from the boundary conditions. One can then obtain the exact expressions for the reflection (R_e) and tunneling (T_e) coefficients (see Appendix V).

The reflection and tunneling coefficients calculated from our variational R -matrix and analytical methods are plotted in Fig. 2 for different values of particle energy E (in units of hartree). As E increases it becomes easier for the particles to tunnel through the barrier – thus the tunneling coefficient increases (and the reflection coefficient decreases as $R + T = 1$). For $E \approx 1.1$ hartree, the reflection and tunneling probability curves cross each other. At this value of energy the probabilities of reflection and transmission are each equal to 50%.

When the energy of the particles are just over the maximum height, $V_0 B$ of the truncated linear step potential, i.e. $E \approx 1.5$ hartree, we would expect classically to see 100% transmission. But from Fig. 2 we find the transmission probability to be about 77%. This reflection of particles for energies greater than the barrier height is also a quantum mechanical effect just as the transmission of particles for energies less than the barrier height is a quantum mechanical effect.

FIG. 2. Transmission T (filled circles) and reflection R (filled squares) coefficients through the truncated linear step potential barrier as a function of particle energy E . The solid (long-dashed) lines are for the exact values of T_e (R_e) obtained from the analytical expression. For the wave-functions $\psi_2(x)$ and $\tilde{\psi}_2(x)$ we have used $\lambda(b) = 1$, $\tilde{\lambda}(b) = 4$, and $\kappa_i = \{0.1 : 0.1 : 6.0\}(\text{bohr})^{-1}$ as our input parameters.

As a check of the accuracy of our calculation we have calculated the average energy E_{av} using Eq. 21 and compared with the actual input energy E and have found that errors are in the range 0.03% – 1.75%. The higher errors occur for smaller values of the input energy, which suggests that more κ_i 's are required.

In Table I we have compared the tunneling coefficients for different values of B obtained from our variational method (VRM) with results from other methods. The reason for choosing different values of B for the truncated linear step potential is to compare with existing data from other numerical methods [10,18]. It is known that the semi-classical WKB approximation fails close to the turning points (i.e. whenever $E - V(x) \approx 0$) – so those points are not taken into account in the WKB calculation. Hence, changes in the B values have no effect on the transmission coefficient. In the modified WKB (MWKB) approximation the turning points are included and thus the transmission coefficient changes with changes in the B values. However the results are 5% – 14% higher than

TABLE I. Comparison of the variation of tunneling coefficients for different values of B with different methods for truncated linear step potential.

B	VRM	ANA	TM	MAT	WKB	MWKB	MAF

6	0.4819	0.4818	0.4818	0.4815	0.4670	0.5163	0.4856
8	0.4374	0.4370	0.4370	0.4374	0.4670	0.4522	0.4377
15	0.3424	0.3423	0.3423	0.3416	0.4670	0.3353	0.3431
20	0.3053	0.3052	0.3052	0.3048	0.4670	0.2917	0.3050

the expected results. The variational results are in excellent agreement with the exact results and results from the numerical transfer matrix (TM), matrix (MAT), and modified Airy functions (MAF) methods. A good agreement of MAF results with the exact results is expected, as for the truncated linear step potential the Airy functions are the exact solutions of the Schrödinger equation.

B. Truncated exponential step potential

The truncated exponential step function, shown in Fig. 3, is another example encountered in planar waveguides [19]. The potential is characterized by the function

$$V(x) = \begin{cases} 0, & x < a \\ V_0 e^{-(x-a)}, & a \leq x \leq b \\ 0, & x > b \end{cases} \quad (26)$$

FIG. 3. The truncated exponential step potential with $V_0 = 0.5$ hartree. The potential is truncated at $a = 1$ and $b = 8$ bohr.

For this potential an analytical solution of the Schrödinger equation exists, which can be written in terms of the modified Bessel functions of first and second kinds $I(\nu, z)$ and $K(\nu, z)$ [21],

$$\psi_2(x) = a_2 K \left(2ik, 2\alpha^{1/2} e^{-(x-a)/2} \right) + b_2 I \left(-2ik, 2\alpha^{1/2} e^{-(x-a)/2} \right), \quad (27)$$

where $k = \sqrt{2mE/\hbar^2}$ and $\alpha = 2mV_0/\hbar^2$. Using these wave-functions we have calculated the exact values of T_e and R_e (see Appendix V). Fig. 4 shows the results of our variational calculation and the analytical calculation. The reflection and tunneling probability curves cross each other for $E \approx 0.13$ hartree. Over the maximum height, V_0 of the potential, i.e. $E \approx 0.5$ hartree we find from Fig. 4, the transmission probability to be about 92%. Compared to the truncated linear step potential the transmission coefficient increases at a faster rate for the truncated exponential step function. This is expected as the slope of the truncated exponential potential decreases as $-(V_0/a) \exp(-x/a)$ whereas the slope of the truncated linear step potential remains constant at $-V_0$.

FIG. 4. Transmission T (filled circles) and reflection R (filled squares) coefficients through the truncated exponential step potential barrier. Solid (long-dashed) lines are for the exact values of T_e (R_e) obtained from the analytical expression. Different input parameters are $\lambda(b) = 2$, $\bar{\lambda}(b) = 8$, and $\kappa_i = \{0.1 : 0.1 : 6.0\}$.

We have compared the calculated E_{av} values with the input E values to check the accuracy of our calculation and have found that the error is between 0.013% – 2.1% of the input energy values. This again shows that a denser grid of κ_i 's is needed for smaller E values.

Our variational results (VRM) are compared to other methods in Table II [10,18]. Here we find that the numerical transfer matrix (TM) and matrix (MAT) methods give the same results as the analytical results. An inspection of Table II shows that the results of our vari-

TABLE II. Comparison of the variation of tunneling coefficients for different values of E/V_0 with different methods for truncated exponential step potential.

E/V_0	VRM	ANA	TM	MAT	WKB	MWKB	MAF

ational R -matrix method are within 0.56% of the analytical results (ANA); however, one should note that the agreement is improved as E increases. Other methods such as WKB and MWKB again fail to provide satisfactory results. Although MAF results are much more accurate than the WKB and MWKB results but it is less accurate (differs from exact results by 0.35% – 1.5%) than our variational results.

C. Truncated parabolic potential

The truncated parabolic potential illustrated in Fig. 5 is of considerable interest in fiber and integrated optical waveguides [19]. The profile of the potential is given by,

$$V(x) = \begin{cases} 0, & x < a \\ V_0 [B^2 - (x - x_0)^2], & a \leq x \leq b \\ 0, & x > b \end{cases} \quad (28)$$

FIG. 5. Parabolic potential truncated at $x = x_0 \pm B$ bohr. We have chosen $V_0 = 0.5$ hartree, $x_0 = 2$ bohr and $B = 1$ bohr for our calculation.

In Fig. 6 we have plotted our variational R -matrix results for the transmission and reflection coefficients. Here the particle with $E \approx 0.27$ hartree have equal reflection and transmission probabilities. The transmission probability is 74% when the particle energy just exceeds the maximum height $V_0 B^2$ of the barrier.

FIG. 6. Transmission T (filled circles) and reflection R (filled squares) coefficients through the truncated parabolic potential barrier. The exact values for T_e and R_e are not known in this case. The lines are drawn only to guide the eyes. Input parameters used are $\lambda(b) = 2$, $\tilde{\lambda}(b) = 3$, and $\kappa_i = \{0.1, 0.5, 0.9, 1.3, 2.0, 2.4, 3.0, 3.4, 4.0, 4.4, 5.0, 5.4, 6.0\} (\text{bohr})^{-1}$.

TABLE III. Comparison of the variation of tunneling coefficients for different values of E/V_0 with different methods for truncated parabolic potential.

E/V_0	VRM	TM	MAT	WKB	MAF	MMAF
0.10	0.1122	0.1124	0.1122	0.0575	0.0390	0.0971
0.20	0.2139	0.2141	0.2141	0.0778	0.0506	0.1859
0.50	0.4599	0.4604	0.4603	0.1878	0.1003	0.3981

When compared to our E_{av} values with the input E values we obtained a satisfactory agreement as the errors are within 2%. Our variational results are compared with results from other numerical methods for three different values of E/V_0 in Table III [10,18]. The exact analytical results for T_e and R_e are unavailable in this case. This comparison show that our results from variational R -matrix method is in excellent agreement with transfer matrix and matrix methods. In this case also, WKB, MAF, and MMAF does not provide any satisfactory results.

D. Truncated bell-shaped potential

Our next example is the smooth bell shaped potential defined by

$$V(x) = \frac{V_0}{\cosh^2(x - x_0)}, \quad (29)$$

where x_0 is a constant.

FIG. 7. Bell-shaped potential with $V_0 = 2$ hartree and $x_0 = 5$ bohr. Inner region is defined between $x = 1$ bohr and $x = 9$ bohr. Potentials V_1 in region I and V_3 in region III are assumed to be zero.

An exact solution of the wave-function of the particle in region II for this potential barrier is known and can be written in terms of the hypergeometric functions [20]. Transmission and reflection coefficients can then be calculated. The exact tunneling coefficient is given by (for $8V_0 > 1$, which is our case) the closed form expression,

$$T_e = \frac{\sinh^2(\pi k)}{\sinh^2(\pi k) + \cosh^2(\pi \beta/2)}, \quad (30)$$

where $k = \sqrt{2mE/\hbar^2}$ and $\beta = \sqrt{8mV_0/\hbar^2} - 1$. In this case our calculated E_{av} values differ from the input E values by 0.0065% – 0.694%. For the truncated bell-shaped potential we are unable to compare with other numerical methods as we have not found any existing numerical results. Fig. 8 illustrates our variational results and the exact results. At larger values of the energy E our values of T and R deviate slightly from the exact values which again suggests that a better and optimized choice of κ_i is necessary to obtain better accuracy. From Fig. 8 we find that the transmission coefficient is about 62% when E is over the peak of the barrier.

E. Eckart's potential

Eckart introduced a smoothly varying potential function defined as

$$V(x) = \frac{1}{2} \left[A \frac{e^{x-x_0}}{1 + e^{x-x_0}} + B \frac{e^{x-x_0}}{(1 + e^{x-x_0})^2} \right], \quad (31)$$

where A and B are two dimensionless arbitrary parameters [22]. The shape of the potential is shown in Fig. 9.

FIG. 8. Transmission T (filled circles) and reflection R (filled squares) coefficients through the bell-shaped potential barrier. Solid and long-dashed lines are for the exact values of T_e and R_e . Input parameters used are $\lambda(b) = 1$, $\tilde{\lambda}(b) = 9$, and $\kappa_i = \{0.1 : 0.2 : 3.0\}$.

The Schrödinger equation for this potential leads to a differential equation of hypergeometric type, whose solutions can be written down in terms of the hypergeometric functions from which the exact coefficients of reflection and transmission can be extracted [1,22]. The exact expression of R_e is given by (for $B > 1/4$)

$$R_e = \frac{\cosh(2\pi(k - \beta)) + \cosh(2\pi\delta)}{\cosh(2\pi(k + \beta)) + \cosh(2\pi\delta)}, \quad (32)$$

where $k = \sqrt{2mE/\hbar^2}$, $\beta = \sqrt{k^2 - A}$, and $\delta = \sqrt{B - 1/4}$. The coefficient T_e is obtained using the relation $T_e = 1 - R_e$. The computed values of T, R and the exact values T_e, R_e are shown in Fig. 10. Our variational results for T and R are in good agreement with the exact results. From Fig. 10 we find that almost all the particles are transmitted to region III when their energies are just above the maximum height of the barrier, which is at 2.23 hartree. For large values of E there are some discrepancies between the two results which could be improved by enlarging and optimizing the set of κ_i . Note that in this case also we have not found any data using other numerical techniques for comparison. For this case, the errors for E_{av} compared to the input E values are within 0.078% – 1.43%.

IV. CONCLUSION

We have applied the variational R -matrix method to calculate the reflection and tunneling probabilities of par-

FIG. 9. Eckart potential with $A = 1$, $B = 8$, and $x_0 = 8$ bohr. Inner region is defined between $x = 2$ bohr and $x = 13$ bohr. Potentials V_1 and V_3 are approximately constants and their values are evaluated at the boundary values, i.e. $V_1 = V(x)|_{x=1}$ and $V_3 = V(x)|_{x=13}$. The particle energies E are taken to be larger than V_1 and V_3 .

ticles tunneling through five one-dimensional potential profiles – truncated linear step, truncated exponential step, truncated parabolic, bell shaped, and Eckart. We have compared our results with results from analytical and other numerical methods and found satisfactory agreement with the analytical results and some of the numerical results obtained using numerical matrix and transfer matrix techniques. Our results can be improved by a better choice of a larger and optimized basis set. We have checked this by enlarging the basis sets for the truncated linear and exponential potential steps. Although semi-classical WKB method is a simple method but it is restricted to slowly varying potentials that are continuous. For potentials with discontinuities WKB approximation fails. In modified WKB approximation this deficiency is taken into consideration, but still it fails to provide satisfactory results for any general potential. Modified Airy function and improved MAF methods are suitable only for certain potentials such as the truncated linear step, truncated parabolic, and truncated quartic potentials. Although the matrix method and the transfer matrix technique yield satisfactory results but they are complicated. On the other hand the variational R -matrix method is simple, general, easy to implement, and applies to any potential shape. Also it is non-iterative and thus computationally efficient. This method can be applied in scattering theory and also in quantum tunneling in two and three dimensions.

The authors thank S. T. Powell and A. Lahamer for helpful discussions and suggestions and gratefully acknowledge the support by the Undergraduate Research and Creative Projects Program of Berea College.

FIG. 10. Transmission T (filled circles) and reflection R (filled squares) coefficients for the Eckart potential. Solid and long-dashed lines are for the exact values of T_e and R_e obtained from the analytical expression in Eq. 32. Input parameters used for this calculation are $\lambda(b) = 2$, $\bar{\lambda}(b) = 13$, and $\kappa_i = \{0.001 : 0.2 : 3.0\}$.

V. APPENDIX

We assume that for a potential $V(x)$ the Schrödinger equation (Eq. 1) can be solved exactly for the inner region defined by $a \leq x \leq b$ and the solution is given in terms of two functions $f(x)$ and $g(x)$ as

$$\psi_2(x) = a_2 f(x) + b_2 g(x). \quad (33)$$

For example, for the truncated linear step potential the functions $f(x)$ and $g(x)$ are the Airy functions $Ai(x)$ and $Bi(x)$ and for the truncated exponential step potential they are the modified Bessel functions $K(\nu, z)$ and $I(\nu, z)$. We now match the wave functions $\psi_1(x)$, $\psi_2(x)$ ($\psi_2(x)$, $\psi_3(x)$) and their derivatives at $x = a$ (at $x = b$) and solve the set of simultaneous equations to obtain the coefficients a_i and b_i 's ($i = 1, 2, 3$). Using these coefficients an exact expression for the tunneling coefficient can be obtained which is given by,

$$T_e = 4 \left(\frac{k_3}{k_1} \right) \left| \frac{N}{D} \right|^2, \quad (34)$$

where the numerator N and the denominator D are,

$$\begin{aligned} N &= [f(b)g'(b) - g(b)f'(b)], \\ D &= \left[g'(b) - ik_3 g(b) \right] \left[1 - \frac{i}{k_1} f'(a) \right] \\ &\quad - \left[f'(b) - ik_3 f(b) \right] \left[1 - \frac{i}{k_1} g'(a) \right]. \end{aligned}$$
